

# DNA Computing

Molecular Computation of Solutions to  
Combinatorial Problems

by Leonard M. Adleman in 1994

# Overview

- Motivation (DHP Problem)
- The Approach by Dr. Aldeman using DNA Computing
- Pros and Cons of the Approach

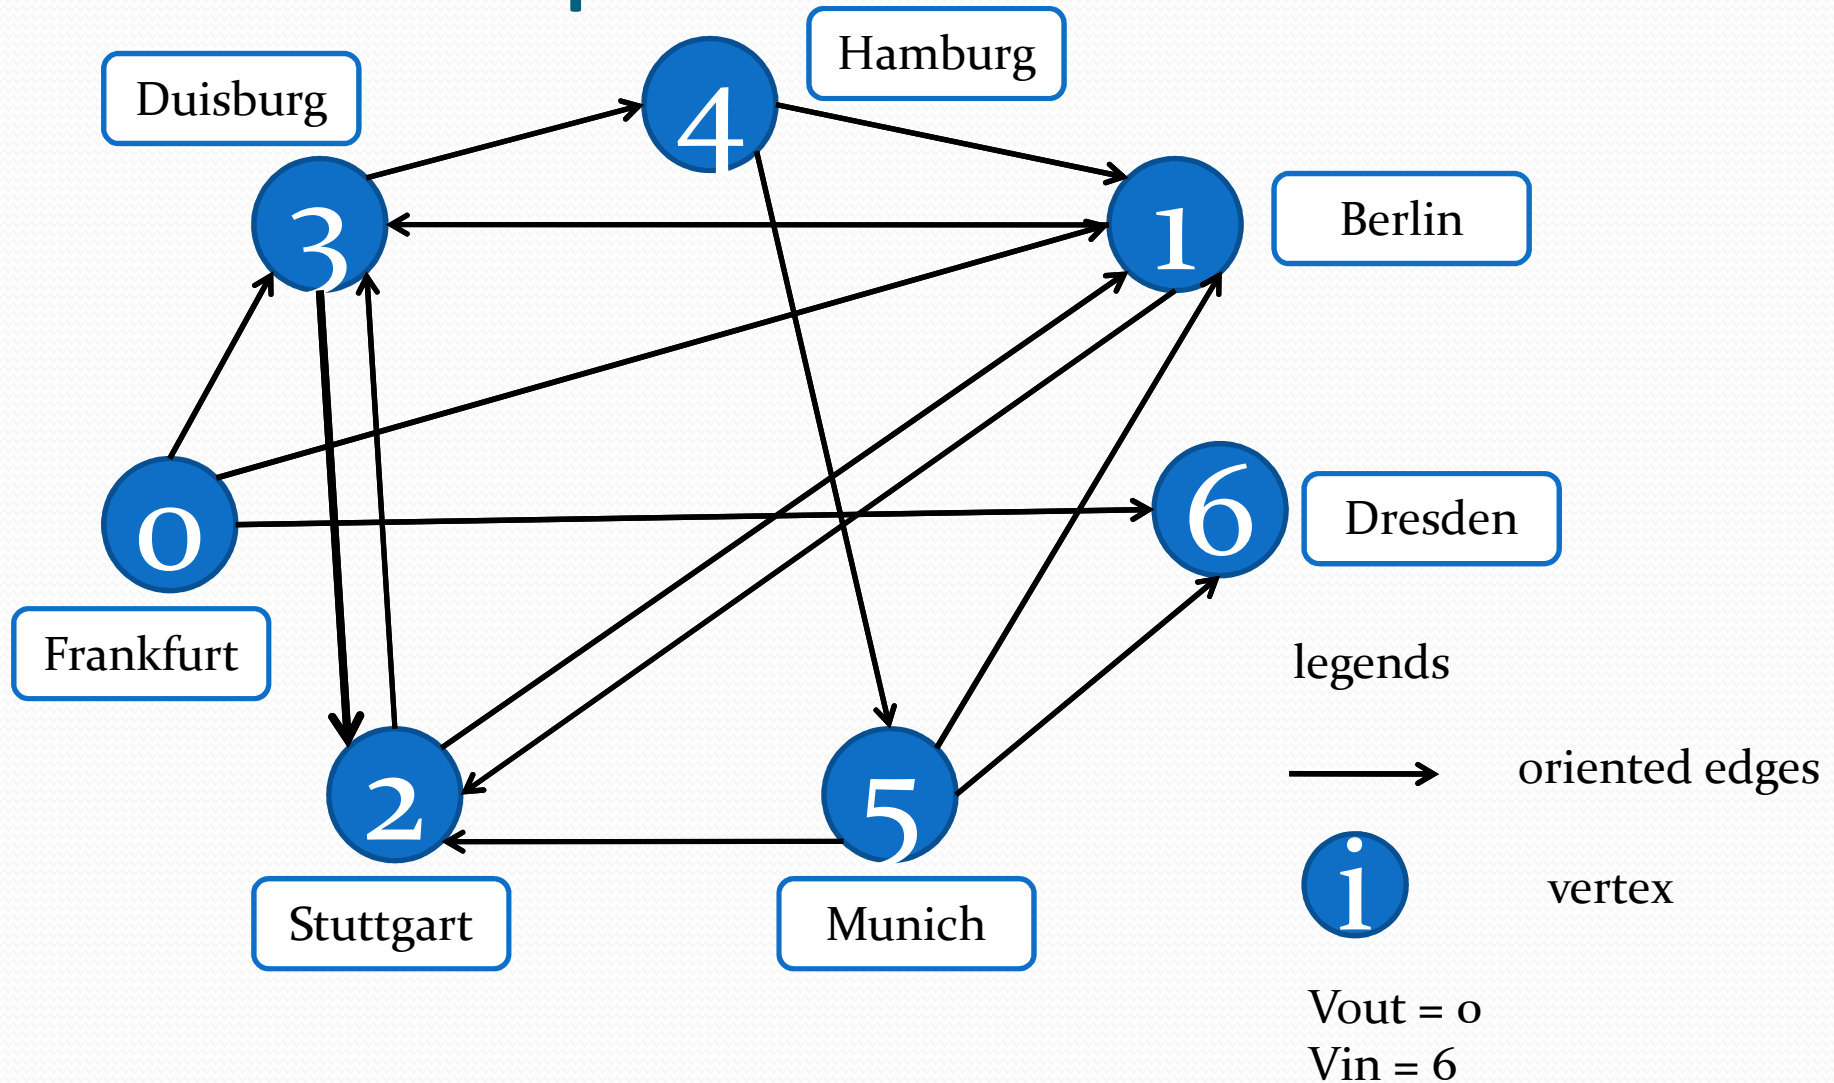

# Motivation

- Directed Hamiltonian Path (DHP) Problem

Given: an oriented graph, which consists of points (**vertices**) and of arrows (**oriented edges**).

Problem: find a path through the graph that starts and ends at the given vertices ( $V_{in}$  and  $V_{out}$ ) and includes every other vertex exactly once.

# Example of DHP Problem

# Nondeterministic Algorithm by Aldeman

1. Generate Random paths through the graph
2. From all paths created in step 1, keep only those that start at  $V_{in}$  and end at  $V_{out}$
3. From all remaining paths, keep only those that visit exactly  $n$  vertices.
4. From all remaining paths, keep only those that visit each vertex at least once.
5. if any path remains, return “yes”; otherwise, return “no”.

# Step 1: Generate Random paths

- each vertex  $i$  in the graph is associated with a random 20-mer sequence of DNA denoted  $O_i$ .

$O_2 = \text{ACTACGATTCCAGTACGACT}$

$O_3 = \text{GGTACAGTCCATGAGCGTAT}$

$O_4 = \text{CTGTGACAAGTCACGACTAT}$

- The reverse complementary strand is  $\underline{O_i}$

$\underline{O_2} = \text{AGTCGTAAGTCCATGAGCGTAT}$

$\underline{O_3} = \text{ATACGCTCATGGACTGTACC}$

$\underline{O_4} = \text{ATAGTCGTGACTTGTCACAG}$

# Step 1: Generate Random paths

- Each edge  $i \rightarrow j$  is presented by an oligonucleotide  $O_{i \rightarrow j}$  that is the 3' 10-mer of  $O_i$  followed by the 5' 10-mer of  $O_j$

$O_2 = \text{ACTACGATTCCAGTACGACT}$

$O_3 = \text{GGTACAGTCCATGAGCGTAT}$

$O_4 = \text{CTGTGACAAGTCACGACTAT}$

$O_{2 \rightarrow 3} = \text{CAGTACGACTGGTACAGTCC}$

$O_{3 \rightarrow 4} = \text{ATGAGCGTATCTGTGACAA}$

- For the edges  $O_{i \rightarrow j}$  involved the begin and end (begin  $i = 0$ ; end  $j = 6$ )

$O_{0 \rightarrow j}$  consists of 3' 20-mer of  $O_0$  and 5' 10-mer of  $O_j$

$O_{i \rightarrow 6}$  consists of 3' 10-mer of  $O_i$  and 5' 10-mer of  $O_6$

- Because DNA has a 3' end and a 5' end

$O_{2 \rightarrow 3} \neq O_{3 \rightarrow 2}$  (Preserves edge orientation)

# Step 1: Generate Random paths

- 50 pmol of  $\underline{O}_i$  and 50 pmol of  $O_{i \rightarrow j}$  are mixed together in a single ligation reaction

- $\underline{O}_i$  serves as splints to bring  $O_{i \rightarrow j}$   
Through ligation many random paths will be created

# Step 1: Generate Random paths

- Examples of random paths

## Step 2: keep paths that start at $V_{in}$ and end at $V_{out}$

- The product of Step 1 is amplified by PCR using primers  $O_0$  and  $O_6$   
-> only those molecules encoding paths that begin with vertex 0 and end with vertex 6 are amplified

Problem:

$O_0 \rightarrow 3$	$O_3 \rightarrow 4$	$O_4 \rightarrow 5$	$O_5 \rightarrow 6$	
$O_0$	$O_3$	$O_4$	$O_5$	$O_6$

## Step 3: keep only those that visit exactly 7 vertices

- The product of Step 2 is run on an agarose gel and the 140 bp band ( for 7 vertices) was excised and soaked in ddH<sub>2</sub>O
- The product was PCR-amplified and gel-purified several times to enhance its purity

O <sub>0</sub> ->3	O <sub>3</sub> ->4	O <sub>4</sub> ->5	O <sub>5</sub> ->4	O <sub>4</sub> ->5	O <sub>5</sub> ->6	
<u>O<sub>0</sub></u>	<u>O<sub>3</sub></u>	<u>O<sub>4</sub></u>	<u>O<sub>5</sub></u>	<u>O<sub>4</sub></u>	<u>O<sub>5</sub></u>	<u>O<sub>6</sub></u>

## Step 4: keep only those that visit each vertex at least once.

- From the product from Step 3 single stranded DNA are generated.

PCR using primers Oo and biotinylated O6

# Step 4: keep only those that visit each vertex at least once.

- ssDNA is annealed with biotinylated O<sub>1</sub>

- the complex is immobilized with MAGNET and then the sample is washed several times  
-> only ssDNA with O<sub>1</sub> remain
- Process is repeated successively with biotinylated O<sub>2</sub>, O<sub>3</sub>, O<sub>4</sub>, O<sub>5</sub> -> the remaining ssDNA has the right answer

# Step 5: Get The Answer

- Dr. Aldeman used “Graduated PCR”

PCR with primers of  $O_0$  and  $\underline{O}_i$  in the path the now the position of vertex  $i$  read the length of the PCR product

example: for vertex 3

primers:  $O_0$  and  $\underline{O}_3$

$O_0 \rightarrow 1$	$O_1 \rightarrow 2$	$O_2 \rightarrow 3$	$O_3 \rightarrow 4$	$O_4 \rightarrow 5$	$O_5 \rightarrow 6$	
$\underline{O}_0$	$\underline{O}_1$	$\underline{O}_2$	$\underline{O}_3$	$\underline{O}_4$	$\underline{O}_5$	$\underline{O}_6$

A band of 80 bp  $\rightarrow 80/20 = 4$  th position in the sequence

# Step 5: Get The Answer

- Today:

sequencing

# Scale up

- It took 7 days to done the whole experiment.  
This Proof-of-concept experiment -> can be scaled up for 100 vertices
- 1. Ligation of the oligos for the edges and the vertecices
- 2. PCR with  $O_0$  and  $O_{99}$
- 3. Cut the right band (2000bp)
- 4. Using biotin-avidin magnetic beads system
- 5. Sequencing

It would last half a year or even more, still it is faster than normal approach.

# Advantages of DNA Computing

- Theoretical higher performance (operation per second)  
one molecule is one operation  
 $10^{20}$  molecules operated in a week  $\approx 1.65 * 10^{14}$  operation per sec  
( $10^{12}$ )
- Remarkable energy efficiency  
theoretical maximum of  $34 * 10^{19}$  operations per joule ( $10^9$ )

# Disadvantages of DNA Computings

- Amount of DNA grow exponentially with the complexity of problems
  - >for 200 cities we would require an amount of DNA that weighed more than the Earth.
- Unexpected errors because of unspecific hybridization
- requires human assistance
- DNA degradation
